

Before thinking about converting manual tests to automated tests, ask yourself below questions. If you have the answers, go for it. If not, then don't automate.

1. Why are you automating the tests? Is it to reduce regression cycle time or to provide quick feedback on the build quality?
2. How do you plan to provide this quick feedback? Do you have the CICD pipeline ready? Who is going to build & maintain it?
3. Do you have the skill set to automate the manual tests?
4. Do you have enough bandwidth? Would this be a side hustle or a full fledged development activity?
5. What's your plan to automate new test cases? Do you plan to automate in the same sprint or next sprint?
6. What's your plan to update automation with application changes?
7. Is your app testable? Does it have unique locators? Is the dev open to make app code changes to support automation?
8. Do you have Unit & API tests? If not, do you plan to follow the test pyramid? If not, do you plan to rely completely on UI tests?
9. What infrastructure do you plan to run your automation on? Do you have a managed cloud setup or unmanaged cloud setup? Who builds and maintains it?
10. Do you have access to APIs, DBs, creating & destroying test data programmatically?

11. If the manual test case gets updated, how do you plan to update the automated test?
12. Have you thought about automating requirements instead? If yes, then why not automate requirements? Wouldn't automating manual tests add unnecessary layer in between?
13. How often would automation run? Every commit, once a day?
14. Who looks at the reports and what would be your action plan for automated test failures?
15. How and when do you plan to communicate application changes in the SDLC/Agile process flow so that automation is updated and ready to test? Would automation be part of DOD? Would app testability be part of DOR?
16. What would be your source control strategy? PR, etc.?
17. What would be your plan to maintain the quality of automation code? Any design patterns you are going to follow? What would be your quality check points?

There can be many more questions. Most of these should be addressed in automation plan or strategy and it should be in place even before the developer writes the first line of code.

If that's not in place, most likely you will end up doing a side activity with limited bandwidth, limited or no support from the team, with QAs having limited

automation skillset.

This can probably end in a mess.
